# CS 188: Artificial Intelligence Fall 2011

Lecture 5: CSPs II 9/8/2011

Dan Klein – UC Berkeley

Multiple slides over the course adapted from either Stuart Russell or Andrew Moore

# Today

- Efficient Solution of CSPs
- Local Search

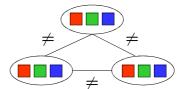

2 l

#### Reminder: CSPs

- CSPs:
  - Variables
  - Domains
  - Constraints
    - Implicit (provide code to compute)
    - Explicit (provide a subset of the possible tuples)
    - Unary / Binary / N-ary

- Usually: find any solution
- Find all, find best, etc

2

## **Backtracking Search**

```
function Backtracking-Search(csp) returns solution/failure return Recursive-Backtracking(\{\ \}, csp)

function Recursive-Backtracking(assignment, csp) returns soln/failure if assignment is complete then return assignment var \leftarrow \text{Select-Unassigned-Variable}(\text{Variables}[csp], assignment, csp) for each value in Order-Domain-Values(var, assignment, csp) do if value is consistent with assignment given Constraints[csp] then add \{var = value\} to assignment result \leftarrow \text{Recursive-Backtracking}(assignment, csp) if result \neq failure then return result remove \{var = value\} from assignment return failure
```

## Improving Backtracking

- General-purpose ideas give huge gains in speed
  - ... but it's all still NP-hard
- Ordering (last class):
  - Which variable should be assigned next?
  - In what order should its values be tried?
- Filtering: Can we detect inevitable failure early?
- Structure: Can we exploit the problem structure?

5

## Filtering: Forward Checking

- Idea: Keep track of remaining legal values for unassigned variables (using immediate constraints)
- Idea: Terminate when any variable has no legal values

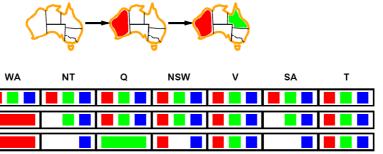

[demo: forward checking animation] 6

#### Filtering: Constraint Propagation

 Forward checking propagates information from assigned to unassigned variables, but doesn't provide early detection for all failures:

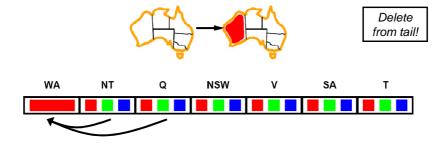

- NT and SA cannot both be blue!
- Why didn't we detect this yet?
- Constraint propagation propagates from constraint to constraint

7

# Consistency of An Arc

An arc X → Y is consistent iff for every x in the tail there is some y in the head which could be assigned without violating a constraint

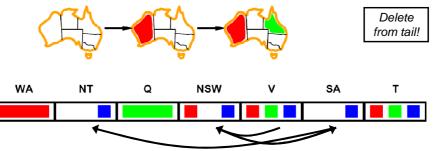

- What happens?
- Forward checking = Enforcing consistency of each arc pointing to the new assignment

## Arc Consistency of a CSP

A simple form of propagation makes sure all arcs are consistent:

- If X loses a value, (incoming) neighbors of X need to be rechecked!
- Arc consistency detects failure earlier than forward checking
- What's the downside of enforcing arc consistency?
- Can be run as a preprocessor or after each assignment

ç

#### **Establishing Arc Consistency**

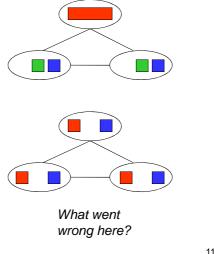

```
function AC-3( csp) returns the CSP, possibly with reduced domains inputs: csp, a binary CSP with variables \{X_1, X_2, \ldots, X_n\} local variables: queue, a queue of arcs, initially all the arcs in csp while queue is not empty do (X_i, X_j) \leftarrow \text{REMOVE-FIRST}(queue) if \text{REMOVE-INCONSISTENT-VALUES}(X_i, X_j) then for each X_k in \text{NEIGHBORS}[X_i] do add (X_k, X_i) to queue function \text{REMOVE-INCONSISTENT-VALUES}(X_i, X_j) returns true iff succeeds removed \leftarrow false for each x in \text{DOMAIN}[X_i] do if no value y in \text{DOMAIN}[X_i] allows (x, y) to satisfy the constraint X_i \leftrightarrow X_j then delete x from \text{DOMAIN}[X_i]; removed \leftarrow true return removed
```

- Runtime: O(n<sup>2</sup>d<sup>3</sup>), can be reduced to O(n<sup>2</sup>d<sup>2</sup>)
- ... but detecting all possible future problems is NP-hard why?

[DEMO]

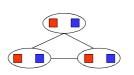

#### **Limitations of Arc Consistency**

- After running arc consistency:
  - Can have one solution left
  - Can have multiple solutions left
  - Can have no solutions left (and not know it)

# K-Consistency

- Increasing degrees of consistency
  - 1-Consistency (Node Consistency): Each single node's domain has a value which meets that node's unary constraints
  - 2-Consistency (Arc Consistency): For each pair of nodes, any consistent assignment to one can be extended to the other
  - K-Consistency: For each k nodes, any consistent assignment to k-1 can be extended to the kth node.
- Higher k more expensive to compute
- (You need to know the k=2 algorithm)

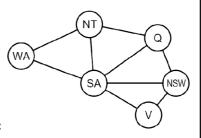

## Strong K-Consistency

- Strong k-consistency: also k-1, k-2, ... 1 consistent
- Claim: strong n-consistency means we can solve without backtracking!
- Why?
  - Choose any assignment to any variable
  - Choose a new variable
  - By 2-consistency, there is a choice consistent with the first
  - Choose a new variable
  - By 3-consistency, there is a choice consistent with the first 2
  - ..
- Lots of middle ground between arc consistency and nconsistency! (e.g. path consistency)

12

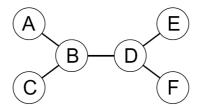

#### **Problem Structure**

- Tasmania and mainland are independent subproblems
- Identifiable as connected components of constraint graph
- Suppose each subproblem has c variables out of n total
  - Worst-case solution cost is O((n/c)(d<sup>c</sup>)), linear in n
  - E.g., n = 80, d = 2, c = 20
  - 2<sup>80</sup> = 4 billion years at 10 million nodes/sec
  - (4)(2<sup>20</sup>) = 0.4 seconds at 10 million nodes/sec

 $\left(\mathsf{T}\right)$ 

#### Tree-Structured CSPs

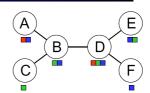

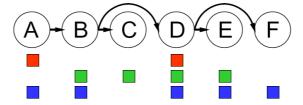

- Theorem: if the constraint graph has no loops, the CSP can be solved in O(n d²) time
  - Compare to general CSPs, where worst-case time is O(dn)
- This property also applies to probabilistic reasoning (later): an important example of the relation between syntactic restrictions and the complexity of reasoning.

15

#### Tree-Structured CSPs

 Choose a variable as root, order variables from root to leaves such that every node's parent precedes it in the ordering

- For i = n : 2, apply RemoveInconsistent(Parent(X<sub>i</sub>),X<sub>i</sub>)
- For i = 1 : n, assign X<sub>i</sub> consistently with Parent(X<sub>i</sub>)
- Runtime: O(n d<sup>2</sup>) (why?)

#### Tree-Structured CSPs

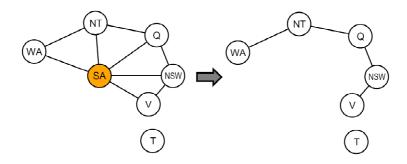

- Why does this work?
- Claim: After processing the right k nodes, given any satisfying assignment to the rest, the right k can be assigned (left to right) without backtracking
- Proof: Induction on position

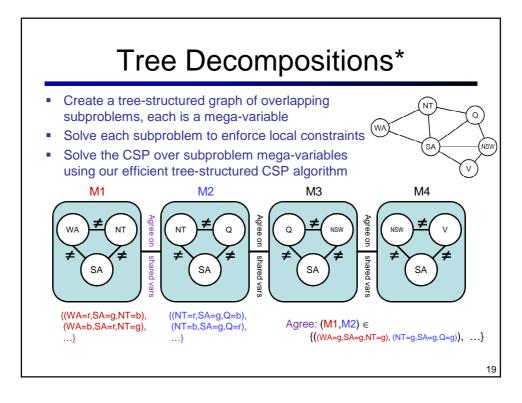

- Why doesn't this algorithm work with loops?
- Note: we'll see this basic idea again with Bayes' nets

17

# Nearly Tree-Structured CSPs

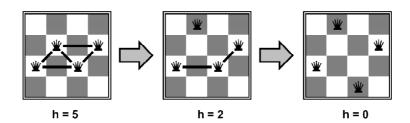

- Conditioning: instantiate a variable, prune its neighbors' domains
- Cutset conditioning: instantiate (in all ways) a set of variables such that the remaining constraint graph is a tree
- Cutset size c gives runtime O( (dc) (n-c) d2), very fast for small c

## Iterative Algorithms for CSPs

- Local search methods typically work with "complete" states, i.e., all variables assigned
- To apply to CSPs:
  - Start with some assignment with unsatisfied constraints
  - Operators reassign variable values
  - No fringe! Live on the edge.
- Variable selection: randomly select any conflicted variable
- Value selection by min-conflicts heuristic:
  - Choose a value that violates the fewest constraints
  - I.e., hill climb with h(n) = total number of violated constraints

## Example: 4-Queens

- States: 4 queens in 4 columns (4<sup>4</sup> = 256 states)
- Operators: move queen in column
- Goal test: no attacks
- Evaluation: c(n) = number of attacks

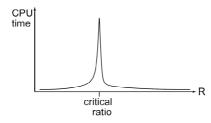

[DEMO]

~4

#### Performance of Min-Conflicts

- Given random initial state, can solve n-queens in almost constant time for arbitrary n with high probability (e.g., n = 10,000,000)
- The same appears to be true for any randomly-generated CSP except in a narrow range of the ratio

$$R = \frac{\text{number of constraints}}{\text{number of variables}}$$

# Summary

- CSPs are a special kind of search problem:
  - States defined by values of a fixed set of variables
  - Goal test defined by constraints on variable values
- Backtracking = depth-first search with one legal variable assigned per node
- Variable ordering and value selection heuristics help significantly
- Forward checking prevents assignments that guarantee later failure
- Constraint propagation (e.g., enforcing arc consistency) does additional work to constrain values and detect inconsistencies
- Constraint graphs allow for analysis of problem structure
- Tree-structured CSPs can be solved in linear time
- Iterative min-conflicts is usually effective in practice
